

SECURITY AS A SERVICE

Castles of medieval times had multiple layers of defense. The most common was to have a moat, outer castle walls and then finally an inner keep. As the threats became more sophisticated in the medieval age, the castles had to adapt with multiple types of defenses. The same thing is happening today with network security. No longer are the basic firewalls and antivirus software good enough to ward off the multiple types of attacks that have appeared on the threat landscape in recent months. This requires a new, layered approach that must be used to ensure adequate protection.

L1

Antivirus/Antimalware - still comprises the cornerstone and last line of defense for each server and workstation

L2

WebProtection - additional layer of protection that keeps employees away from the “darker” parts of the internet and blocks bad downloads

L3

MailProtection - stops spam and viruses before they ever reach the user’s mailbox, also provides continuity during an email outage

L4

Patch Management - keeps all of your at-risk software and operating systems up to date with latest security patches

L5

Backup - when all else fails, or in the event of total disaster, a combination of local and cloud backup keeps your data safe

The presence of crypto-type viruses has made it no longer a luxury to employ multiple layers of security and most critically, reliable offsite backup. Think about it this way. Due to the ever-changing variants of viruses, antivirus software is no longer as effective against the onslaught of zero-day infections. That is why the additional layers shown above matter. Criminals make money not only stealing your data but encrypting it so that you no longer have access and then holding the unlock key for ransom.

We now offer all 5 of these layers in one, low-cost package that also includes monitoring the health of your servers and workstations. You pay only for the number of servers and workstations you use on a monthly basis and there is no long-term contract.
